

Smartphone App Store Rating Breakdown

Ali Ramy

April 21, 2026

1 Abstract

This project examines Google Play Store data to find relationships between app categories and user ratings. By cleaning the data and using analysis techniques, we provide useful insights into market competition for app developers.

2 Description

The dataset was taken from Kaggle and includes app categories, install counts, and user ratings. The main variables used were Category and Rating, which helped measure the average performance of apps in different sectors.

3 Data Cleaning

Missing values (NaN) in the Rating column were replaced with a neutral value of 4.0. This helped keep the data consistent and allowed accurate analysis and calculations.

4 Data Modeling

A Star Schema was used to improve the analysis process. A custom Date Table was created using the CALENDARAUTO() function, and a many-to-one relationship was linked to the main dataset to allow time-based filtering.

5 Dashboard

The final dashboard highlights the average rating by category.

6 Conclusion

Our analysis shows that niche app categories often have higher average ratings. We recommend that developers focus on quality and regular updates to keep ratings above 4.0, which is important for long-term user retention.
